## Abstract

During a survey of polypores in the montane forest of the Ôbo de São Tomé National Park, in the western African, equatorial island of São Tomé, a specimen that was, a priori, related to *Fomitopsis* showed deviating features including subglobose basidiospores with a large gutta. The gross morphology of the basidiome, the hyphal system, the subglobose basidiospores and a brown rot pointed toward *Niveoporofomes*. Phylogenetic inferences based on multiple loci dataset (ITS-LSU-SSU-*TEF1-RPB2*) confirmed the placement, and *Niveoporofomes oboensis* is described as new. The species is compared to *Fomitopsis widdringtoniae*, known from southeast Africa, which is characterized also by subglobose basidiospores; hence, the new combination *N. widdringtoniae* is proposed. The new combination *Niveoporofomes globosporus* (basionym *Trametes globospora*) is also proposed based on phylogenetic analyses. A key to the species of *Fomitopsis*, *Niveoporofomes*, *Rhodofomes* and *Rhodofomitopsis* in Tropical Africa is presented.

## Introduction

*Fomitopsidaceae*, typified by *Fomitopsis* P. Karst., is a family of brown rot polypores, mostly spanning over temperate areas (Han et al. 2016; Justo et al. 2017). The family (also referred to as the *Antrodia* clade) was revised by Han et al. (2016) and *Fomitopsis*, as previously widely accepted (or *sensu lato*, e.g. Ryvarden and Johansen 1980), was shown to be polyphyletic. Consequently, *Fomitopsis* species were reclassified into several new or reinstated genera, including *Fragifomes*,

*Niveoporofomes*, *Rhodofomes*, *Rhodofomitopsis* or still *Rubellofomes* (Han et al. 2016).

In tropical Africa, *Fomitopsis* s.l. were represented by seven species (Ryvarden and Johansen 1980; Masuka and Ryvarden 1993; Mossebo and Ryvarden 1997). However, considering the current treatment of *Fomitopsidaceae* (Han et al. 2016), *Rhodofomes* and *Rhodofomitopsis* occur also in Tropical Africa, represented by *Rhodofomes carneus* (as *Fomitopsis carnea* (Blume & T. Nees) Imazeki, Ryvarden and Johansen 1980) and *Rhodofomitopsis africana* (as

*Fomitopsis africana* Mossebo & Ryvarden, Mossebo and Ryvarden 1997).

As part of an ongoing survey of polypores (*Basidiomycota*) in sub-Saharan Africa (Decock and Mossebo 2001, 2002; Decock 2001, 2007, 2011a, b; Decock and Ryvarden 2002, 2015, 2020; Decock and Masuka 2003; Decock et al. 2005, 2021; Amalfi et al. 2010; Yombiyeni et al. 2011; Decock and Bitew 2012), a specimen from the African, equatorial island of São Tomé, collected at Ôbo de São Tomé National Park, was shown to belong to *Niveoporofomes* based on morphology and [ITS-LSU-SSU-*TEF1*-*RPB2*]-based phylogenetic inferences. It is interpreted as representing a distinct, undescribed species, proposed as *Niveoporofomes oboensis*. This species is compared to *Fomitopsis widdringtoniae* Masuka & Ryvarden, known from south-eastern Africa, which has identical basidiospores (Masuka and Ryvarden 1993). A key to the species of *Fomitopsis*, *Niveoporofomes*, *Rhodofomes* and *Rhodofomitopsis* in Tropical Africa is presented.

*Niveoporofomes* has been proposed to host *Fomitopsis spraguei*, a species that deviates from *Fomitopsis pinicola* and species of other related genera in having obovoid to broadly ellipsoid basidiospores with a large gutta. The genus was up to now considered monospecific (Han et al. 2016). Analyses of available ITS sequences showed that sensu Han et al. (2016), *N. spraguei* is not monophyletic, but encompasses several clades that could represent each a distinct species, of which *N. globosporus* that is proposed as a new combination.

## Materials and methods

### Material and collection localities

The type specimen originated from mid-elevation forest at elev. ~ 1300 masl at Ôbo de São Tomé National Park in São Tomé, which vegetation is the Afromontane Equatorial rainforest (Carvalho et al. 2004). The type specimen is preserved at O, with isotypes at BR and MUCL (herbarium acronyms according to Thiers (Thiers 2016) continuously updated (<http://sciweb.nybg.org/science2/IndexHerbariorum.asp>).

### Description

Colours are described according to Korerup and Wanscher (Korerup and Wanscher 1981). Sections were carefully dissected under a stereomicroscope in hot (40 °C) NaOH 3% solution and later examined in NaOH 3% solution at room temperature (Decock et al. 2010). Sections were also examined in Melzer's reagent and lactic acid Cotton blue to show staining reaction. All the microscopic measurements were done in Melzer's reagent. In presenting the size range of

several microscopic elements, 5% of the measurements at each end of the range are given in parentheses when relevant. In the text, the following abbreviations are used: av. = arithmetic mean, R = the ratio of length/width of basidiospores and  $av_R$  = arithmetic mean of the ratio R.

## Molecular study and phylogenetic analysis

DNA extraction, amplification and sequencing of the 5' end of the nuclear ribosomal 28S rRNA gene (region including the domains D1–D3), the ITS regions (including 5.8S), the nuclear SSU regions, partial *TEF1*-alpha gene (*TEF1*) and the region between domains 6 and 7 of the second largest subunit of the RNA polymerase II (*RPB2*), were as described in Amalfi et al. (2012) and Han et al. (2016). The sequences were assembled in Geneious Pro v. 6.0.6 (Biomatters). Materials and sequences used in this study are listed in Table 1.

Nucleotide sequences were automatically aligned using the MUSCLE algorithm (Edgar 2004) with default settings. The alignment was further optimised and manually adjusted as necessary by direct examination with the software Se-AL v. 2.0a11 (University of Oxford).

Two datasets were constructed and used for further phylogenetic analyses respectively at family and genus level. A combined dataset combined nuclear ribosomal partial LSU, ITS-5.8S and SSU; partial *TEF1*; and *RPB2* genes sequences from 75 collections (Online Resource 1), including the outgroup (*Neolentiporus maculatissimus* strain Rajchenberg 158, (Han et al. 2016)). A second dataset combined the ITS-5.8S sequences of 23 collections (Online Resource 2), including all nineteen *Niveoporofomes* sequences available in public databases (based on a > 95.0% sequence similarity threshold, on 22/04/2021), with *Fomitopsis betulina* strain (CBS 378.51) as outgroup (Han et al. 2016).

The assignment of codon positions in the protein-coding sequences was confirmed by translating nucleotide sequences into predicted amino acid sequences using Mac-Clade 4.0 (Maddison and Maddison 2005) and then compared with the annotated *Fomitopsis pinicola* isolate AFTOL-ID 770 sequences.

Potential ambiguously aligned segments, especially in the introns present in *TEF1* and in the ITS-5.8S alignment, were detected by Gblocks v0.91b (Castresana 2000) (<http://molevol.cmima.csic.es/castresana/Gblocks.html>), with the following parameter settings: minimum number of sequences for a conserved position = 38 (minimum possible); minimum number of sequences for a flank position = 38 (minimum possible); maximum number of contiguous non-conserved positions = 4 bp, minimum block size = 4 bp and gaps allowed within selected blocks in half of the sequences.

To detect the possible bias from substitution saturation and to evaluate the phylogenetic signal, we tested each partition of

the combined dataset and the ITS-5.8S dataset by using Xia's test (Xia et al. 2003; Xia and Lemey 2009), as implemented in DAMBE (Xia and Xie 2001). As the *Iss.c* is based on simulation results, there is a problem with more than 32 species. To circumvent this problem, DAMBE was used to randomly sample subsets of 4, 8, 16 and 32 OTUs multiple times and to perform the test for each subset to see if substitution saturation exists for these subsets of sequences. In order to confirm the results of the Xia's method, we also plotted the raw number of transversions and transitions against Tamura-Nei genetic distances with the aid of the DAMBE package, with an asymptotic relationship indicating the presence of saturation. Models of evolution for BI were estimated using the Akaike information criterion (AIC) as implemented in Modeltest 3.7 (Posada and Crandall 1998). The combined dataset was subdivided into 7 data partitions: ITS, LSU, SSU, *TEF1* 1st and 2nd codon positions, *TEF1* 3rd codon positions and *RPB2* 1st and 2nd codon positions, and *RPB2* 3rd codon positions. The three introns present in *TEF1* and the one present at the end of *RPB2* sequences were excluded from the phylogenetic inferences because judged too ambiguous to be confidently aligned (*TEF1*) or because were missing in most of the sequences (*RPB2*). Phylogenetic analyses were performed separately for each individual and concatenated loci using Bayesian Inference (BI) as implemented in MrBayes v3.2 (Ronquist et al. 2011) and maximum likelihood (ML) as implemented in RAxML 7.2.7 (Stamatakis et al. 2008). The best-fit models for each partition were implemented as partition specific models within partitioned mixed-model analyses of the combined dataset (Table 2, Online Resource 3). All parameters were unlinked across partitions. Bayesian analyses were implemented with two independent runs, each with four simultaneous independent chains for six million generations for both combined and ITS datasets, starting from random trees and keeping one tree every 1000th generation. All trees sampled after convergence (average standard deviation of split frequencies < 0.01 and confirmed using Tracer v1.4 (Rambaut and Drummond 2007) were used to reconstruct a 50% majority-rule consensus tree (BC) and to calculate Bayesian posterior probabilities (BPP). BPP of each node was estimated based on the frequency at which the node was resolved amongst the sampled trees with the consensus option of 50% majority-rule (Simmons et al. 2004). A probability of 0.95 was considered significant. ML searches conducted with RAxML involved 1000 replicates under the GTRGAMMAI model, with all model parameters estimated by the programme. In addition, 1000 bootstrap (ML BS) replicates were run with the same GTRGAMMAI model. We provided an additional alignment partition file to force RAxML software to search for a separate evolution model for each dataset. Clades with maximum likelihood bootstrap values of 75% or greater were considered supported by the data.

To detect topological conflicts amongst data partitions, the nodes between the majority-rule consensus trees obtained in the ML analysis from the individual datasets were compared with the software *compat.py* (available at [www.lutzonilab.net/downloads](http://www.lutzonilab.net/downloads)). Paired trees were examined for conflicts only involving nodes with ML BS > 75% (Mason-Gamer and Kellogg 1996; Reeb et al. 2004; Lutzoni et al. 2004). A conflict was assumed to be significant if two different relationships for the same set of taxa (one being monophyletic and the other not) were observed in rival trees. Sequence data and statistical analysis for each individual dataset and combined analysis are provided in Table 2 (Online Resource 3).

## Results

### Phylogenetic analysis

By comparing the tree topologies obtained for the individual datasets, no significant conflict involving significantly supported nodes was found using the 75% ML BP criterion; the datasets were therefore combined.

The test of substitution saturation (Table 2, Online Resource 3) showed that the observed index of substitution saturation (*Iss*) for the restricted ITS-5.8S dataset, the *TEF1* (1st and 2nd codon positions, and 3rd codon position), *RPB2* (each codon positions), nucLSU and nucSSU alignments of the combined dataset was significantly lower than the corresponding critical index substitution saturation (*Iss.c*), indicating that there was little saturation in our sequences ( $P < 0.001$ ). On the other hand, the ITS-5.8S partition of the combined dataset, the *TEF1* introns and the *RPB2* intron showed sign of substitution saturation, indicating the unsuitability of these data for phylogenetic analysis. Nevertheless, reanalysing the ITS partition with DAMBE after that Gblocks retained 402 sites (51% of a total of 771 sites), the substitution saturation test revealed an *Iss* value that was significantly ( $P < 0.001$ ) lower than the *Iss.c* (Table 2, Online Resource 3), indicating the suitability of this data for further phylogenetic analysis. We therefore included the ITS-5.8S partition in the combined dataset, excluding the poorly aligned positions identified by Gblocks as well as the *TEF1* and the *RPB2* introns partitions.

The *Niveoporofomes s.s* ITS-5.8S dataset and the *Fomitopsis s.l.* combined [ITS-LSU-SSU-*TEF1*-*RPB2*] data set comprised 23 and 75 taxa respectively including the outgroups and, once excluded the introns, were of 668 and 4149 sites long including gaps, respectively. Sequence data, evolutionary models and statistical analysis for each dataset are provided in Table 2 (Online Resource 3). For the combined dataset the two Bayesian runs (6,000,000 generations) converged to stable likelihood values after 1,615,000 generations; therefore, 4385 stationary trees from each analysis were used to compute a 50% majority rule

consensus tree in PAUP\* to calculate posterior probabilities. For the ITS-5.8S dataset, the two Bayesian runs (4,000,000 generation) converged after 460,000 generations and 3540 stationary trees from each analysis were used to compute a 50% majority rule consensus tree in PAUP\* to calculate posterior probabilities.

In the ML searches, the ITS-5.8S alignment had 154 distinct patterns with a proportion of gaps and undetermined characters of 11.95%. In the ML searches with RAxML, the combined dataset alignment had 1530 distinct patterns with a proportion of gaps and undetermined characters of 37.99%. The consensus of the BI and the maximum likelihood tree were nearly identical. The BI consensus trees for the combined and ITS-5.8S only datasets are presented in Figs. 1 and 2 respectively. The topologies of the trees regarding the recovery and the relative positions of the different taxa of the *Fomitopsis* complex were, overall, similar in all the phylogenetic inferences, and in accordance with previous published results (Ortiz-Santana et al. 2013; Han et al. 2016), at least for what concerns significantly supported branches.

The phylogenetic analyses recovered our specimen from Ôbo de São Tomé National Park in the vicinity of *N. spraguei*, forming a distinct branch (Fig. 1). On this basis and morphological characters, of which the subglobose, obovoid basidiospores with a large gutta, the specimen is interpreted as representing an undescribed species proposed below as *Niveoporofomes oboensis*.

The collections of *N. spraguei*, available on GenBank, segregated into three clades (Fig. 2). The collections originating from the USA and a single one from Europe clustered in a sister position to a clade that includes sequences from the holotype of *Trametes globospora* Ryvarden & Aime (Belize, Ryvarden et al. 2009) and two other collections from Mexico (KR135353, JX434660). The *N. spraguei* collections originating from Asia formed a third basal clade, suggesting that they represent a likely cryptic species.

## Taxonomy

*Niveoporofomes oboensis* Decock, Amalfi & Ryvarden sp. nov. (MB 841205) Fig. 3

*Niveoporofomes oboensis* is characterized by the combination of a pileate, slightly decurrent basidiome, a white pore surface, discolouring to brownish on bruising when fresh, 3.5–4 pores/mm, a pseudodimitic to dimitic hyphal system with hyaline clamped generative hyphae, dominated in the contextual trama by sclerified, thick-walled, septate, and clamped hyphae, with long aseptate segment and dominated in the hymenophoral trama by skeletal hyphae, and broadly obovoid to subglobose basidiospores with a large gutta, mostly 4.7–5.5 × 4.0–4.5 (– 4.8) µm (ave = 5.2 × 4.3 µm).

Holotype: São Tomé, Ôbo de São Tomé National Park, on the way to Lagoa Amelia, approx. N 00°16.95'–E 006°35.48', elev. 1300 masl, on buttress of a living tree, *Olea capensis* (*Oleaceae*), 12 April 2011, Cony Decock, ST-11-04, Holotype in O, Isotypes in BR and MUCL (MUCL53518) (living strain ex holotype MUCL 53518).

*Basidiome* annual, pileate, with a slightly decurrent pore surface, corky when fresh, drying hard corky to woody; *pileus* solitary or imbricated with to 2 pilei superposed, broadly attached, elongated, 16–20-cm wide, projecting 8–9.5 cm, applanate in section, 1.5–2-cm thick at the base down to 0.5 at the margin; *pileus surface* white toward the margin, cinnamon to light brown, dark brown to black toward the base, glabrous; *margin* round, whitish, discolouring to brownish on bruising, drying dark greyish; *pore surface* plane to slightly concave, or wavy, whitish when fresh, drying whitish to pale corky; *pores* mostly round, 3.5–4/mm, 180–238 (– 250) µm diam (ave 208 µm) to elliptic, 225–285 × 150–200 µm (ave 251 × 186 µm); *dissepiments* thick, entire, 35–135 µm (ave 66 µm); *context* white, ivory when fresh or dry, dense and hard corky, fibrous, up to 10 mm thick at the base down to 2 mm at the margin; *tube layer* contrasting with the context, yellow white to orange white, pale corky, up to 13 mm high.

*Hyphal system* pseudodimitic (intermediate sensu Pegler 1996) to dimitic; *generative hyphae* in all parts hyaline, thin- to slightly thick-walled, with clamped septa, little branched, 2.0–2.5 µm diam; *context* dominated by sclerified, thick-walled generative hyphae, (3.5–) 4.0–5.0 (–5.5) µm (ave 4.6 µm) in the main part, negative in Melzers reagent, acyanophilous, with large, basal and intermediate clamps, with “spouting” clamps, with aseptate segments of variable length, measured from 50 µm up to 350 µm, reverting to thin-walled generative hyphae or ending in an aborted thin-walled hyphae, or occasionally in a whip-like narrow, unbranched to little branched process; mediate hyphae uncertain; *hymenophoral trama* dominated by skeletal hyphae, originating from a basal clamp or a short mediate hyphae, from 2.2–2.5 µm at the basal septum to 3.0–4.0 (–4.5) µm (ave 3.6 µm) in the main part, measured up to 500 µm long, very thick-walled, hyaline, ending thin-walled, negative in Melzers reagent, acyanophilous, irregularly swelling in alkali.

*Hymenium*: *basidia* clavate to slightly pear-shaped, clamped at the basal septum, with four sterigmata; *basidioles* clavate to slightly pear-shaped, clamped at the basal septum, 16–20 × 6.5–8 µm; cystidioles very few, with a basal clamp, slightly ventricose, bottle-shaped, ~ 17 × 6.0 µm; *basidiospores* subglobose, broadly obovoid, hyaline, thin-walled, smooth, most with a large oil drop (best seen in fresh specimen), (4.5–) 4.7–5.5 (–5.7) × 4.0–4.5 (–4.8) µm (ave = 5.2 × 4.3 µm),  $R = 1.1–1.3$  (ave  $R = 1.2$ ).

*Physiology (type of rot)*: brown rot;

**Ecology (substrate, host, habitat):** on buttress of a living tree, *Olea capensis* (*Oleaceae*), Afrotropical Equatorial rainforest.

**Distribution.** Known from the type locality, Ôbo de São Tomé National Park, São Tomé.

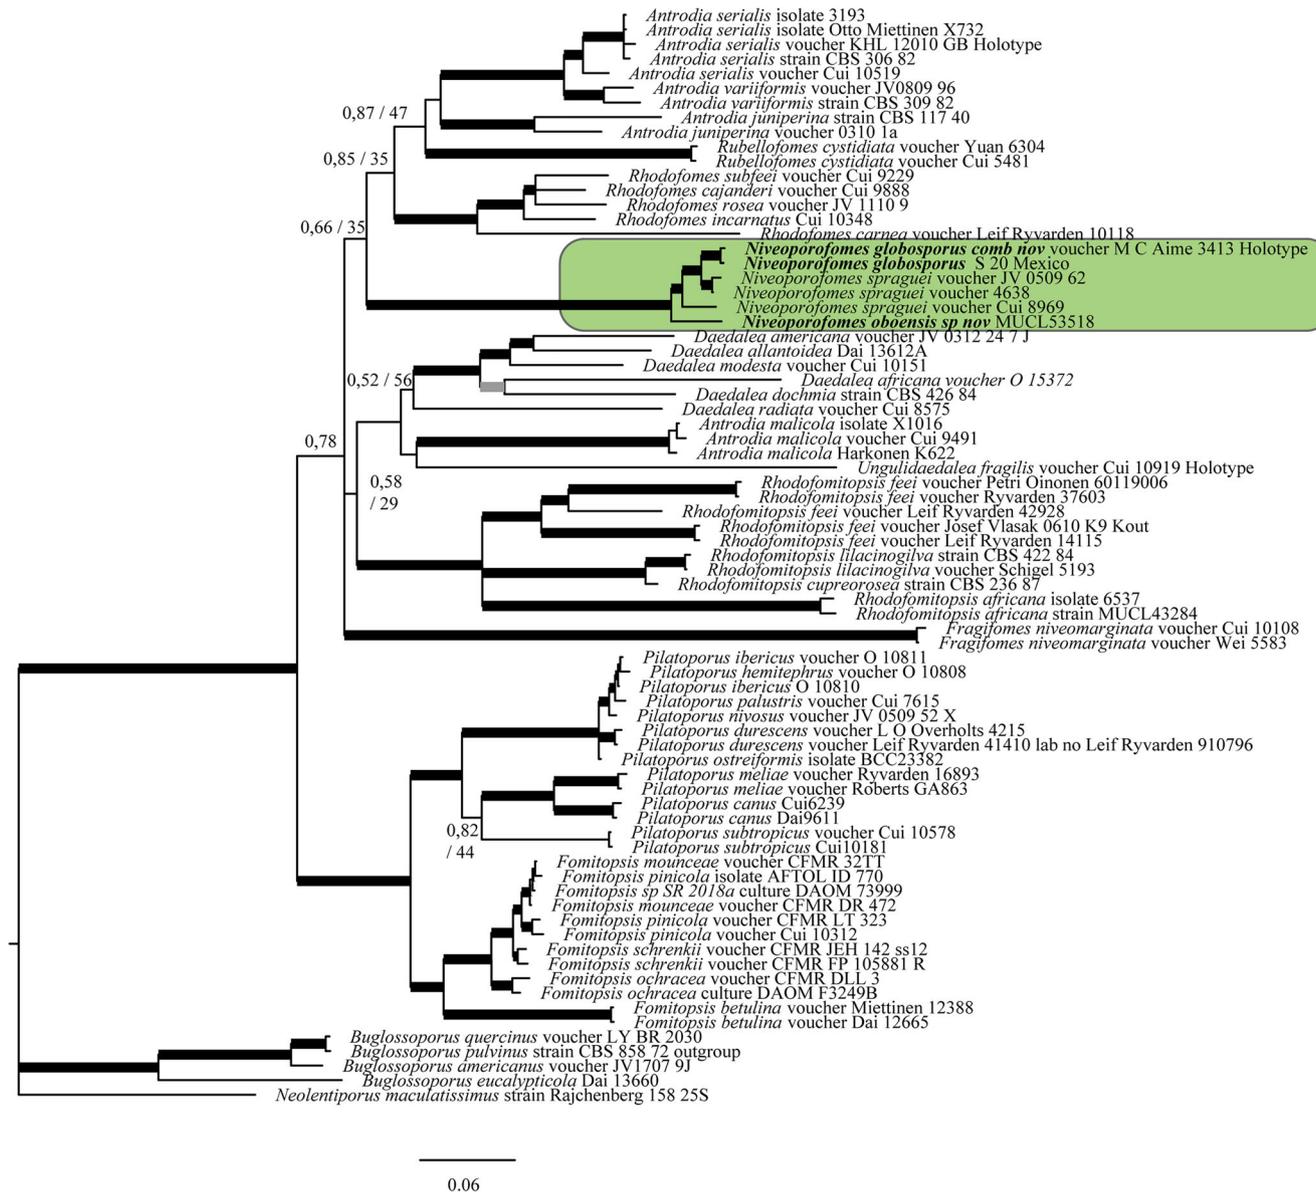

**Phylogenetic affinities:** the sole known phylogenetic relative are, *hitherto*, *N. spraguei* and *T. globospora*.

## Discussion

*Niveoporofomes* was segregated from *Fomitopsis* based on the subglobose to globose basidiospores, which are elliptic

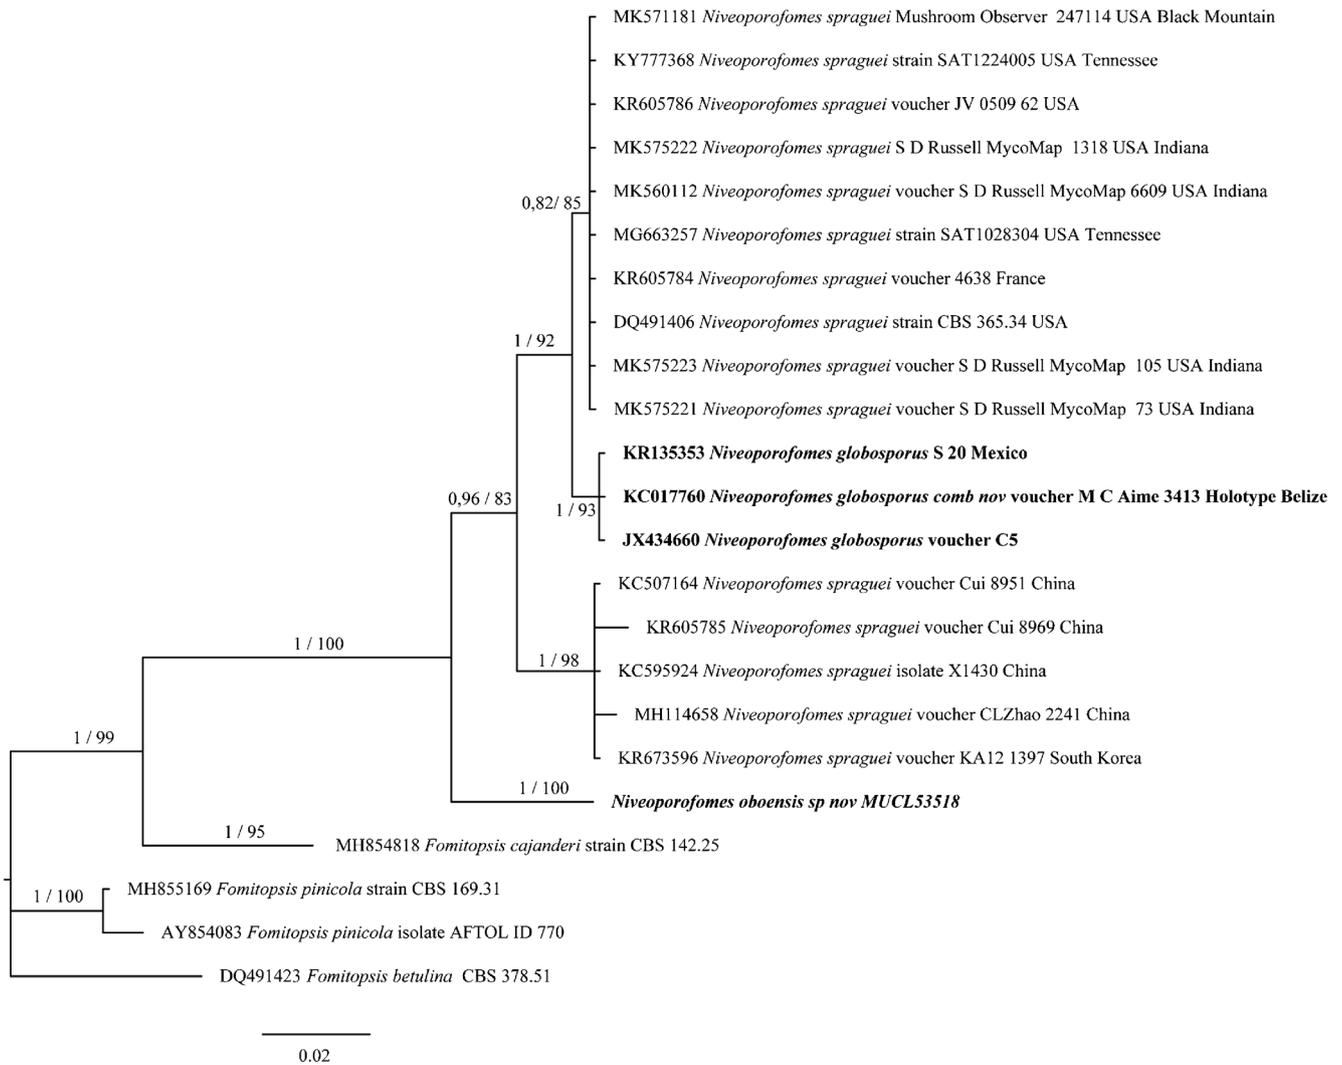

in *Fomitopsis* s.s. and related genera. Multilocus phylogenetic analyses confirmed that *N. spraguei* and *F. pinicola* were not monophyletic.

The hyphal system of *Niveoporofomes* was described as dimitic with “frequently branched” skeletal hyphae (Han et al. 2016). This description is of uncertain interpretation. To characterize skeletal hyphae as “frequently branched” is intrinsically contradictory; skeletal hyphae are, by definition, unbranched, but for the sparingly branched mediate hyphae (Corner 1932). Ryvarden and Melo (Ryvarden and Melo 2014) described the hyphal system as trimitic, with generative, skeletal and binding hyphae. Rivoire (Rivoire 2020) provided a more accurate description of the hyphal system, dominated

**Fig. 1** The 50% majority-rule consensus tree from Bayesian inference of the combined dataset. Thickened branches in bold represent ML BS support greater than 75% and BPP greater than 0.95; thickened branches in

grey denote branches supported by either ML BS or BPP. For selected nodes, ML BS support value and BPP are respectively indicated to the left and right of slashes. The new taxa are highlighted in the shaded box

**Fig. 2** Bayesian Inference consensus tree based on ITS sequence data for species of *Niveoporofomes*, with *Fomitopsis betulina* strain CBS 378.51 as outgroup. Posterior probabilities obtained through Bayesian inference

and bootstrap values (1000 replicates) obtained from Maximum Likelihood analysis are respectively indicated to the left and right of slashes

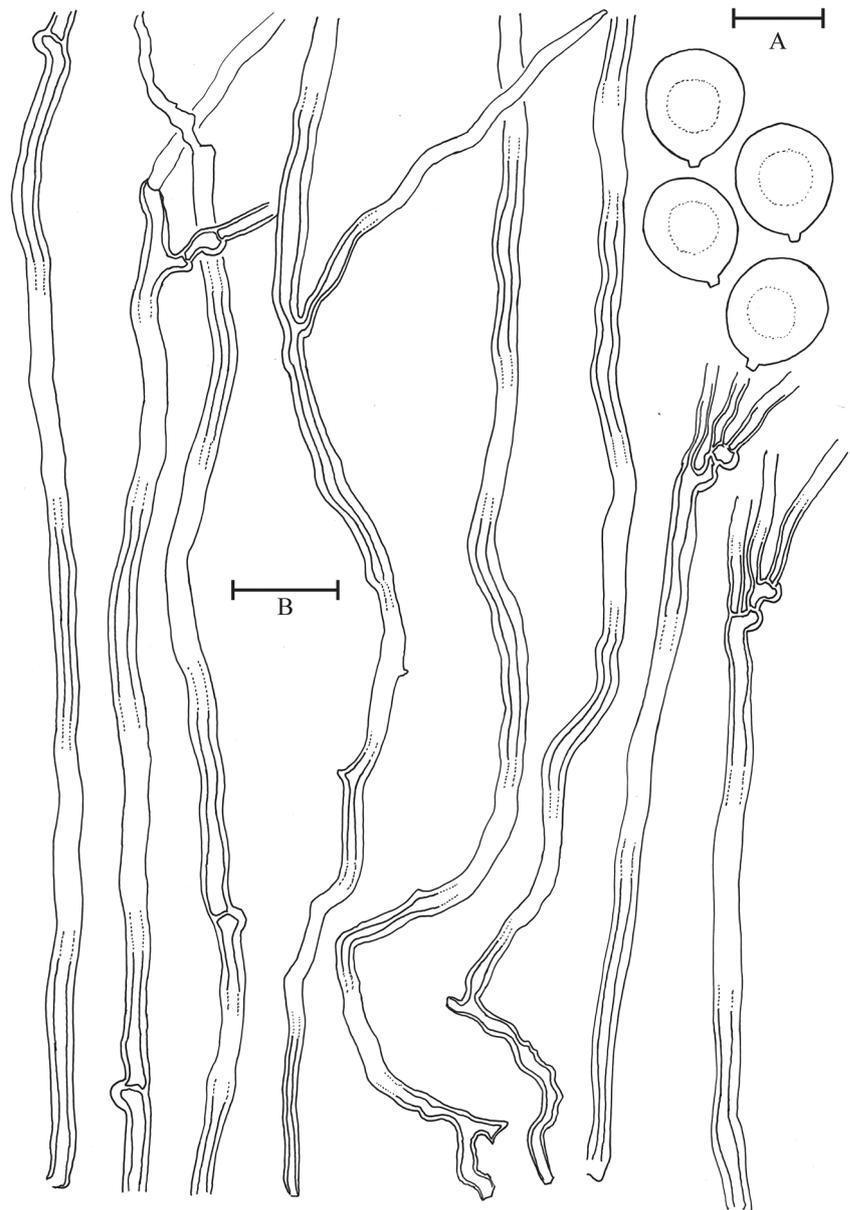

both in the context and the hymenophoral trama by thick-walled [sclerified] generative hyphae, with scarce “skeletal” and “binding” hyphae.

*Niveoporofomes oboensis* and *N. spraguei* share the hyphal system, as described by Rivoire (2020), the subglobose, obovoid basidiospores and a brown rot. Multilocus phylogenetic inference also confirmed their closed affinities. *Niveoporofomes oboensis* differs from *N. spraguei* by a basidiome margin and pore surface tinting brownish when bruised in fresh conditions. These two species also have a disjoint autecology and distribution. The autecology of *N. oboensis*, including the host relationships, habitat, and distribution is known for the type specimen only; it was found on buttresses of *Olea capensis* at Ôbo de São Tomé National Park, in Afromontane Equatorial rainforest (White 1986; Carvalho et al. 2004), whereas *N. spraguei* grows mostly on *Quercus* and *Castanea* in Northern temperate areas

(Gilbertson and Ryvarden 1993; Ryvarden and Gilbertson 1994; Ryvarden and Melo 2014; Rivoire 2020).

In tropical Africa, *F. widdringtoniae* (Masuka and Ryvarden 1993) is the closest morphological relative of *N. oboensis*. The species was described growing on *Widdringtonia nodiflora* (L.) Powrie, a South-eastern African, endemic Gymnosperm (*Cupressaceae*). It is known so far from Malawi only, but may follow its host southernly. It is characterized also by globose basidiospores (Masuka and Ryvarden 1993), what points toward *Niveoporofomes* rather than *Fomitopsis* s.s. Its phylogenetic affinities are unknown, but on the basis of the basidiospores shape and size, and a brown rot, we propose the new combination *Niveoporofomes widdringtoniae* (Masuka & Ryvarden) Decock & Ryvarden, comb. nov., MB839610 (basionym *F. widdringtoniae* Masuka & Ryvarden, Mycol. Helv. 5(2):145, 1993, MB359440).

**Fig. 3** *Niveoporofomes oboensis*, from type ST/11-04, MUCL 56368. Basidiospores (scale bar A = 4  $\mu\text{m}$ ) and vegetative hyphae from the hymenophoral trama (scale bar B = 14  $\mu\text{m}$ )

*Niveoporofomes oboensis* differs from *N. widdringtoniae* in having larger basidiome size, up to 20 cm wide vs up to 5 cm wide, larger pores, 3.5–4 vs. 7–8 pores/mm, and slightly larger basidiospores  $4.7\text{--}5.5$  ( $-5.7$ )  $\times$   $4.0\text{--}4.5$   $\mu\text{m}$ , averaging  $5.2 \times 4.3$   $\mu\text{m}$  vs.  $4.5\text{--}5$   $\mu\text{m}$  in diam, on average  $< 5$   $\mu\text{m}$ . Both species also differ likely in host and distribution range. *Niveoporofomes oboensis* is known from São Tomé on Olea, whereas *N. widdringtoniae* is known from Malawi on *Widdringtonia*, a coniferous host.

*Fomitopsis* s.l. was represented in Tropical Africa by seven species, *F. africana*, *F. carneus*, *F. rhodophaea* (Lev.) Imazeki, *F. scutellata* (Schwein.) Bondartsev & Singer, *F. supina* (Sw.) Ryvar den, *F. widdringtoniae* and *F. zuluensis* (Wakef.) Ryvar den (Ryvar den 1972;

Ryvar den and Johansen 1980; Masuka and Ryvar den 1993; Mossebo and Ryvar den 1997). Currently, *F. zuluensis* would be the sole *Fomitopsis* s.s. recognized still in Tropical Africa, but its phylogenetic affinities are unknown for the time being. *Fomitopsis africana* and *F. carneus* are nowadays accepted in *Rhodofomitopsis* (*R. africana*) and *Rhodofomes* (*R. carneus*) (Han et al. 2016), whereas *F. widdringtoniae* is here accepted in *Niveoporofomes*, a genus now represented by two species in Tropical Africa.

*Fomitopsis rhodophaea*, *F. scutellata* and *F. supina* belong to the white rot genera *Neofomitella* (Li et al. 2014b), *Datroniella* (Li et al. 2014a) and *Fomitella* (Li et al. 2014b), respectively. They are members of the core polyporoid clade

(white rot species, Justo et al. 2017) and not of the *Antrodia* clade (brown rot species).

Brown rot polypores are little diversified in Tropical Africa. They are mostly found inhabiting highland forest ecosystems of Eastern Africa or the Albertine rift, and in the case of *N. oboensis*, a mountain area of western Insular Africa. The notable exception is *R. africana* that was originally described from lowland in Cameroon, on an African non-native host (*Eucalyptus*).

## Notes on *N. spraguei*

*Niveoporofomes spraguei*, as currently accepted (Gilbertson and Ryvarde 1986; Ryvarde and Melo 2014; Han et al. 2016; Rivoire 2020), is a pan-temperate taxon in the Northern hemisphere, growing on various angiosperms, mostly *Quercus* and *Castanea*, both in Europe and North America (Gilbertson and Ryvarde 1986, Ryvarde and Melo 2014, Rivoire 2020).

The phylogenetic analyses based on ITS sequences available at GenBank separated specimens of *N. spraguei* into three clades; an East Asian (China and South Korea) clade, a North American/European clade, and a third, Mesoamerican clade, in an intermediate position, that comprises specimens originating from Mexico and Belize (Fig. 2). The North American/European clade should correspond to *N. spraguei* s.s., in which case, the East Asian clade could represent a distinct taxon. The Mesoamerican clade includes the type of *Trametes globospora*, a species that deviates from all other species of *Trametes* in having globose basidiospores, 4.5–6 µm diam (Ryvarde et al. 2009). Basidiospores are elliptic in all other species of *Trametes*. The new combination *Niveoporofomes globosporus* (Ryvarde & Aime) Decock, Amalfi & Ryvarde comb. nov. (MB839611) is proposed (basionym *Trametes globospora* Ryvarde & Aime, Synopsis Fungorum 26: 28, 2009, MB509818).

## Key to the species of *Fomitopsis*, *Niveoporofomes*, *Rhodofomitopsis*, and *Rhodofomes* found in sub-Saharan, continental and insular Africa

1 Context and pore surface distinctly pinkish (when fresh).....2  
 1' Context and pore surface white, ochraceous, beige, to golden brown.....3  
 2 Pores 3–4 per mm; pileus dark brown; basidiospores cylindrical to navicular.....*Rhodofomitopsis africana*  
 Known hitherto from the lowland rain forest of Cameroon.  
 2' Pores 5–7 per mm; pileus almost black; basidiospores cylindrical to allantoid.....*Rhodofomes carneus*  
 Known from East Africa.

3 Pileus with a reddish to black cuticle; basidiospores elliptic 8–10 µm long.....*Fomitopsis zuluensis* Known hitherto from South Africa.

3' Pileus without cuticle; basidiospores subglobose, obovoid, ≤ 6 µm diam in the longest dimension.....4

4 Pileus white, light to dark brown from the base, bruising greenish; known from *Olea capensis* (*Oleaceae*).....

.....*Niveoporofomes oboensis*  
 Known hitherto from a medium elevation forest of São Tomé.

4' Pileus whitish with some greyish to dirty brown spots; known from *Widdringtonia* (*Cupressaceae*).....

.....*Niveoporofomes widdringtoniae*  
 Known hitherto from the highlands of Malawi.

**Supplementary Information** The online version contains supplementary material available at <https://doi.org/10.1007/s11557-022-01787-z>.

**Acknowledgments** The authors warmly thank the Ministério de Plano e Desenvolvimento, Direcção de Agricultura e Pescas de São Tomé for granting permits to collect in the Obô de São Tomé National Park, and the staff of the Park, and Faustino Oliveira, director of the botanical garden at Bom Sucesso, for the help offered during the collecting trip in April 2011. Mr. Bastien Loloum, Zuntabawe Lda, is warmly thanks also for the logistic aspects of the collecting trip. Cony Decock gratefully acknowledges the financial support received from the Belgian State—Belgian Federal Science Policy and the Fonds de la Recherche Fondamentale Collective (FRFC # 2.4515.06 and FRFC # 2.4.544.10.F). Mario Amalfi gratefully acknowledges the financial support received from Meise Botanic Garden and the Fédération Wallonie-Bruxelles.

**Code availability** Not applicable.

**Author contribution** Mario Amalfi and Cony Decock contributed to the study conception and design. Material collections were performed by Cony Decock. Mario Amalfi produced the sequences and conducted the phylogenetic analyses. The first draft of the manuscript was written by Cony Decock and Mario Amalfi, and all authors commented on previous versions of the manuscript. All authors read and approved the final manuscript.

**Funding** Funding was provided to Cony Decock by Belgian State – Belgian Federal Science Policy (BELSPO), through the BCCM program and by the FNRS through a FRFC project (FRFC # 2.4515.06); to Mario Amalfi by the Fédération Wallonie-Bruxelles and Botanic Garden Meise.

**Data availability** Scientific data concerning DNA sequences and DNA data sets are made as supplementary materials (Online Resource 1 and 2), the type specimen of *Niveoporofomes oboensis* sp. nov. is preserved at O, with isotypes at BR and MUCL (herbarium acronyms according to Thiers 2016).

## Declarations

**Ethics approval and consent to participate** Not applicable.

**Consent for publication** All authors are aware and agree with the submission of this manuscript.

**Competing interests** The authors declare no competing interests.
